Spectrum analysis method of cathode copper for metallic
impurities. V. L. Ginzburg, I. N. Gramenitskii, and D. M.
Livshits (Mining and Met., Combining, No. 1, 1956). Zvezdskaya
Lab. 22, (12-3011156). Spectrum analysis methods for
the detn. of Ni, Fe, Pb, Sb, As, Sn, and Zn are de-
scribed. The method is sensitive to within 0.002% (abs.)
for Ni, Bi, Sb, As, and Sn, and to within 0.005% for Fe,
Pb, and Zn. The samples are obtained by drilling the
cathode sheets, and special tests showed that the samples
were not contaminated by the drill. The electrodes for
spectrum analysis were cast from drillings fused in graphite
crucibles, and no changes in concn. were observed in using a
U.S.S.R. standard sample fused with pure Cu which con-
tained only 0.001% Ni and Fe. Details of manipulations
are given.

Title : Accuracy of Photographic Methods of Spectral Analysis

Orig Pub: Zavod. laboratoriya, 1956, 22, No 11, 1331-1333

Abstract: A comparison was made of the accuracy of analyses of fused nickel, copper regulus, fused cobalt and cathodic nickel, according to calibration graphs in Δ S, lg C coordinates, and in accordance with the solid graph method. Determinations were made of Cu, Fe, Au, Pt, Pd, Ni, Si, Mn, Pb, Sb, Bi, Sn, Co, at concentrations from several thousandth to decimal fractions of one percent, with spectrum excitation in arc discharge of direct and alternating current, and photographic recording on plates of type I, II and III. In most instances no substantial differences were found in the magnitude of errors with different calibration graphs.

Title : Spectral Analysis of Nickel in Low-Voltage Spark Using Cast Electrodes.

Orig Pubq : Zavod. laboratoriya, 1956, 22, No 4, 438-440

Abstract : In the determination of copper and iron admixtures in pure nickel, the spectrum is excited by a DG-1 generator, operating in the spark mode (current 2 -- 2.5 amp). The analytic pairs of lines are Cu 3273.96 -- Ni 3286.95 A and Fe 2599.40/57 -- N 2551.01 A. The interval of the determined concentrations of copper and iron is 0.01 -- 0.5%. The mean arithmetic error of the determination ranges from 5 to 9%.

TITLE: The Third Conference of Spectroscopy Analysts of Nonferrous Metallurgy (Tret'ye soveshchaniye spektroskopistov-analitikov tsvetnoy metallurgii)

PERIODICAL: Zavodskaya Laboratoriya, 1958, Vol. 24, Nr 4, pp. 507-508 (USSR)

ABSTRACT: The above mentioned conference took place at Moscow from November 15 to November 20, 1957; it was called by the Scientific-Technical Society of Nonferrous Metallurgy, and was attended by 255 representatives of 175 organizations. The contributions made by I.E. Britske (Gintsvetmet, Moscow) and N.S. Poluektova (Ukrgiremet, Odessa) dealt with questions of flame photometry. The report delivered by L.I. Kononenko dealt with the method of determining zirconium, hafnium, molybdenum and vanadium. An interesting contribution was made by Ye.D. Raykhbaum, Ye.S. Kostyukova, and V.D. Malykh (Irgiremet, Irkutsk) under the title "On some Causes of the Influence Exercised by Chemical Composition on the Results of Ore Analyses". A detailed report by N.A. Makulova (Giprotsvetmetobrabotka, Moscow) dealt with investigations of the rule governing the transition of test material to the emission

cloud. A.A. Frishberg and V.V. Nedler (Nigrizoloto, Moscow) spoke about problems of the physical-chemical theory in connection with chemical reactions during the formation of volatile compounds in the electric arc. V.L. Ginzburg (Noril'skiy Combine) gave a report on the development of a method of determining the temperature intensity of electrodes. The following contributions dealing with special methods of spectral analysis deserve mentioning: The reports by D.M. Shvarts, L.N. Kaporskiy and V.V. Portnova (Gipronikel', Leningrad) and I.S. Nilova (Severonikel', Monchegorsk), which deal with the analysis of zinc, thallium and antimony; the reports by S.M. Solodovnik (Giredmet, Moscow) and others on the analysis of silicon, silicon dioxide and silicic acid; the reports by V.P. Kharpay and G.M. Gusev on the increase of sensitivity in determinations of microadmixture in silver; the contributions made by N.A. Sin'kov and D.M. Livshits (Noril'skiy Combine) deal with the analysis of solutions containing platinum metals. The report delivered by V.O. Khandros and L.N. Filimonov (Giprotsvetmetobrabotka) deals with the problems of the application of quantum-meters. A.G. Krest'yaninov, Yu.I. Stakheyev and Ya.D. Raykhbaum (Irgiredmet) were the first to use photoelectric apparatus for the

direct analysis of ores for lithium. The contribution made by V.V.Nedler dealt with attempts made at using the horizontal electric arc, stabilized by an air current. The reports concerning standards published by the institutes Gintsvetmet, Giprotsvetmetobrabotka, VIAM (all at Moscow), TsNIIolovo (Novosibirsk), Irgiredmet (Irkutsk), Gipronikel' (Leningrad), VNIItsvetmet (Ust'-Kamenogorsk), Ukrigiredmet (Odessa) confirm the work performed by these institutes during recent years. The necessity of centralizing the publishing of standards was stressed, and the industrial production of high-quality spectral carbons and an increased distribution of ordinary spectral carbons was urgently demanded.

TITLE: Determination of Silicon and Other Impurities in Selenium

PERIODICAL: Zavodskaya laboratoriya, 1960, Vol. 26, No. 5, pp. 559-561

TEXT: N. N. Danilova and L. A. Lerner collaborated in the experimental part of the present investigation. A spectrum analysis for determining impurities in selenium was worked out. The calibration samples used were produced by fusing together Si and Se; less Si was used than corresponds to the stoichiometric ratio in the compound SiSe_2 . Thus, it was possible to obtain a chemically stable mixture of SiSe_2 and Se. By increasing the addition of Se, a series of calibration samples was produced up to a Si content of $2 \cdot 10^{-4}\%$. Silicon was determined according to the following spectral lines: Si 2516.12A (from $1 \cdot 10^{-4}$ to $3 \cdot 10^{-3}\%$ of Si), Si 2881.58A (from $2 \cdot 10^{-4}$ to $2 \cdot 10^{-2}\%$ of Si), Si 2514.33A (from $1 \cdot 10^{-3}$ to $5 \cdot 10^{-2}\%$ of Si), Si 2435.16A (from $1 \cdot 10^{-2}$ to $3 \cdot 10^{-1}\%$ of Si). The calibration samples for determining the other impurities in selenium were also prepared by fusing together the initial alloy with pure selenium. The initial alloy was

TITLE: A spectrochemical method for the determination of
impurities in selenium

PERIODICAL: Zhurnal analiticheskoy khimii, v.17, no.9, 1962,
1096-1100

TEXT: A method of determination of small amounts of impurities by their preliminary concentration and subsequent spectral analysis is proposed. The concentration is carried out by distilling a sample of selenium placed on a powdered carbon support at 315°C in a stream of nitrogen oxides. Selenium distills off in the form of SeO₂ while impurities remain in the carbon powder which is then submitted to spectral analysis on carbon electrodes. To increase the sensitivity of the determination of impurities in carbon powder, sodium chloride (0.6%) or potassium chloride (0.3%) are added to the concentrates. The degree of recovery of various elements in the concentrates was tested. According to the degree of recovery the elements were divided into three groups: 1) 70 to 80%, Au, Mg, Sn, Sb, Bi, Te, Al, Cu, Ag; 2) 40 to 50% Cd, As, Fe, Pb, Ti, Mn;

TITLE: Increasing the sensitivity of the spectral determination of impurities in selenium

PERIODICAL: Zavodskaya laboratoriya, v. 28, no. 6, 1962, 682 - 684

TEXT: By adding NaCl (ionization potential $V_i = 5.1$ ev), the V_i eff of the arc plasma may be controlled in such a way that the sensitivity of the impurity determination is increased considerably. Calibration curves ΔS against $\log C$ were plotted for selenium samples with impurity standards in the presence of carbon powder containing various NaCl additions in the counterelectrode. The dependence of the intensity of the spectral lines on V_i eff was determined. V_i eff = 7 - 8 ev, achieved by carbon powder with 1% Na (= 2.5% NaCl), was the optimum. The sensitivity increase results from the ratio $\Delta C = C$ without NaCl / C NaCl. For the elements investigated, the following ΔC values were found: Te 0.46; Hg 0.20; As 0.50; Cd 0.30; Mg 5.0; Ni 2.2; Al 5.5; Au 5.0; Pb 4.0; Bi 2.5; Cu 5.0; Ti 5.0; Card 1/2

TOPIC TAGS: cosmic ray, metagalaxy, ~~space~~, magnetic field, ~~anisotropic pressure~~, galaxy, ~~plasma~~, adiabatic invariant, *cosmic ray anisotropy, rarefied plasma*

ABSTRACT: It has been generally held that in metagalactic space no anisotropy of cosmic rays can exist because the magnetic field of this space is unable to offset the anisotropic pressure of cosmic rays. This, however, has not been borne out by calculations. The problem of anisotropy of cosmic rays and the transition space between a galaxy and the Metagalaxy is considered to be unsolved. V. L. Ginzburg hypothesized that the unsolved problems of cosmic rays are associated with plasma effects in space, especially with cluster and other instabilities in rarified plasma. The transition of the magnetic field from galaxy to metagalactic space occurs smoothly without hindrances. In moving under such conditions, anisotropic cosmic rays preserve the adiabatic invariant and form clusters in the Metagalaxy. The clusters move along magnetic force lines and become unstable, generating their own waves. Instability of the cluster causes turbulent motion in the plasma and

Card 1/2

L 11250-66

ACC NR: AP6002686

isotropic motion of the cluster. A transition region is formed in which the magnetic field becomes turbulent and the movement of cosmic rays isotropic. In this way a solution is found for the unsolved problems of cosmic rays in metagalactic intermediate space. Orig. art. has: 8 formulas. [EC]

SOURCE: AN SSSR. Fizicheskiy institut. Doklady, 1965. Opticheskiye svoystva polivalentnykh metallov i mezhduelektronnoye vzaimodeystviye, 1-9

TOPIC TAGS: electron, gold, aluminum, tin, lead, electron interaction, metal crystal, permittivity, absorption band

ABSTRACT: In polyvalent metals (Al, Sn, Pb), on the one hand, the approximation of weakly bound electrons is adequate, but on the other hand, the concentration of optical electrons N_{opt} is much lower than that of valence electrons N_{val} (by definition, N_{opt} figures in the expression for the permittivity $\epsilon \approx 4 e^2 N_{opt} / m \omega^2$ for optical frequencies ω lying outside the absorption band). This difference can be explained by the influence of interelectronic interaction, since in the theory of the Fermi liquid for crystalline metals $N_{opt} \neq N_{val}$. At the same time, for liquid metals, the equality $N_{opt} = N_{val}$ should take place, and this is indeed observed in practice. Authors are grateful to M. Ya. Azbel' and D. Pays for

TITLE: Cosmic magnetobremstrahlung (synchrotron) radiation¹⁷

SOURCE: Uspekhi fizicheskikh nauk, v. 87, no. 1, 1965, 65-111

TOPIC TAGS: bremsstrahlung, cosmic radiation, particle acceleration, relativistic particle

ABSTRACT: Magnetobremstrahlung theory is reviewed and its role in radioastronomy and astrophysics is described. All of the necessary details are given for the application of the theory to astrophysical problems. Magnetobremstrahlung is rather widespread in space: cosmic radio-radiation in most cases has magnetobremstrahlung characteristics. This holds for the overall galactic radio-radiation, as well as for that from supernova, ordinary and radio galaxies, etc. Magnetobremstrahlung is highly important in the study of the origin of cosmic rays and gamma- and x-ray astronomy. The nature of electromagnetic radiation from accelerating nonrelativistic and super-relativistic particles is discussed, and formulas are derived for individual electrons. This is compared with magnetobremstrahlung from groups of elec-

Card 1/2

ACC NR:

AP6016663

trons, and the Stokes parameters are defined. The influence of cosmic plasma on the propagation and radiation of electromagnetic waves is considered. It is pointed out that magnetobremssstrahlung radiation can be reabsorbed by relativistic particles, and the absorption coefficient is calculated. Certain applications of magnetobremssstrahlung are discussed in relation to cosmic plasma and magnetic instabilities. The more important formulas are summarized without proof. TITLE: Relativistic electrons in the M82 galaxy 2

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 29, no. 10, 1965, 1825-1829

TOPIC TAGS: galaxy, relativistic electron, hot star, Compton effect, bremsstrahlung, pi meson, nebula/M82 galaxy

ABSTRACT: The galaxy M82 (also called NGC 3034 and 3C 231), which is part of the Ursus Major group, is of special interest, since its relatively close position makes possible a comparatively detailed study of the nonsteady-state (explosion) stage of galactic development. It belongs in a special subclass of irregular galaxies whose members are characterized by an anomalously red light, high luminosity, considerable quantities of dusty matter with floccular structure, and the absence of high-luminosity hot stars. In this connection, the authors present formulas for calculating the energies and energy losses of the relativistic electrons in this galaxy - particularly with respect to the total energy of the light-emitting relativistic electrons, the energy losses due

Card 1/2

L 25773-66

ACC NR: AP6016379

to the Compton effect, and the energy losses due to magnetic bremsstrahlung. It is shown that the total flux of Compton γ -rays from M82 equals the Compton losses. An evaluation of the bremsstrahlung flux of γ -rays due to the decay of π^+ -mesons and bremsstrahlung is presented. The magnetic X-ray bremsstrahlung of M82 is evaluated on the assumption that the optical spectral index of M82 is close to the optical index $\alpha = 1.5$ of the Crab Nebula, which is correct only up to the frequency $\nu = 10^{16}$ cps. TITLE: Origin of cosmic rays 12

39

B

SOURCE: Uspekhi fizicheskikh nauk, v. 88, no. 3, 1966, 485-504

TOPIC TAGS: cosmic ray, supernova, astronomic conference, galaxy, electron spectrum

ABSTRACT: It is argued that cosmic rays cannot be of metagalactic origin and that plasma effects are of fundamental importance to the further development of the astrophysics of cosmic rays; this also pertains to the quasars. According to the authors, the principal sources of cosmic rays in the Galaxy are the bursts of supernovae and possibly also explosions of the galactic nucleus. Emphasis is placed on the role of instability in the formation of the boundary of the galactic halo and in the isotropicization of the cosmic rays emerging from the Galaxy into the Metagalaxy. Allowance is made for the new knowledge that has been gained following the Jaipur Conference on Cosmic Rays in 1963. The Ninth International Conference on Cosmic Rays held in London (September 1965) is critically evaluated; at this conference no new proofs in favor of the theory of the metagalactic origin of galactic cosmic rays - unless the highest energies are concerned - were presented. It is shown that studies of the electron spectrum provide a means of verifying the

Card 1/2

UDC: 623.165

0915

1338

L 31467-66

ACC NR: AP6023130

hypothesis that a large part of cosmic rays (or more exactly, their electron component) is generated during powerful explosions of the galactic nucleus. Any proofs refuting this hypothesis would serve as a strong argument in favor of the local metagalactic theory of the origin of cosmic rays, but no such proofs have yet been presented; nevertheless, this theory merits further discussion. 20441: Low-energy x radiation from the radio galaxies (Delivered at the Scientific Session of the Division of General and Applied Physics, AN SSSR, 20 April 1966)

Источники: *Известия Российской академии наук*, т. 89, № 4, 1966, 549-562.

TOPIC TAGS: cosmic radio source, galaxy, x ray emission, x ray astronomy

ABSTRACT: This is a review article stimulated by recent observation of powerful x-ray sources in A-Cygni. It deals with the history of x-ray astronomy since the observation of x radiation from the sun in 1948 and with the main results obtained in x-ray astronomy of the galaxy and of the metagalactic regions. The major sources of cosmic x radiation are listed and their luminosities given. The nature of the cosmic x radiation is discussed and the most important processes which can give rise to x rays are described (bremsstrahlung, characteristic radiation due to atomic transitions, synchrotron radiation, Compton radiation). Estimates of the relative contributions of the different mechanisms are given. Further prospects and the required apparatus are discussed in the conclusion. Orig. art. has: 2 figures and 5 formulas.

Radiation of an electron moving in a crystal with a constant velocity exceeding that of light. V. L. Ginzburg (*J. Physics U.S.S.R.*, 1940, 1, 101-106, cf. preceding abstract). The method already described is applied to the case of an electron moving in a crystal with velocity $>$ that of light. Two non-circular cones of radiation are produced, in which the intensity is not the same on different generatrices. The polarization of the radiation differs from that in an isotropic medium.

AND SEE METALLURGICAL LITERATURE CLASSIFICATION

The quantum theory of light radiation of an electron uniformly moving in a medium. V. L. Ginzburg. *J. Exptl. Theoret. Phys. (U. S. S. R.)* 10, 550 (1940); *J. Phys. (U. S. S. R.)* 2, 441-52 (1940) (in English). Theoretical-math. The directed radiation of light by an electron moving in a medium with a velocity greater than the phase velocity of light in that medium is discussed from the standpoint of quantum theory. For a nonmagnetic electron the results of quantum and classical theory almost coincide; they differ considerably for a nonrelativistic electron described by Pauli-Dirac equations. The difference is related to the non-inertness of the spin. In the extreme relativistic case the radiation of a Dirac electron coincides exactly with that of a classical nonmagnetic electron.

On the paramagnetic effects influencing the radio-wave propagation in the atmosphere. Ginsburg, V. L. C.R. Acad. Sci. URSS, 35, 9, pp. 270-273, 1942 - The earth's magnetic field gives rise to a double refraction and rotation of the plane of polarization of radio waves in the atmosphere. In evaluating these effects, it is ordinarily sufficient to calculate the change in refr. index of the medium containing free electrons, which is brought about by the magnetic field. The paper considers processes of a paramagnetic nature, depending on a const. magnetic moment of the atoms and molecules of gases in the atmosphere. Considerations relating to the electronic states of molecules, atoms and ions of N ₂ and O ₂ lead to formulae from which the magnitude of the effect can be evaluated. The influence of the paramagnetic processes is insignificant.		1991 8

Excited states of elementary particles. V. L. Ginzburg (*Compt. rend. Acad. Sci. U.R.S.S.*, 1943, 27, 9--13).—Two types of difficulty in relativistic quantum particle theory are discussed: (a) difficulties arising from the infinite proper energy of elementary particles; (b) difficulties arising from not taking into account the effect of the proper field of the particle on its scattering properties. If the proper field of the magnetic moment is taken into account, excited spin states of the particle must be postulated, and the wave equation must contain an empirical const.

Relativistic wave equations for particles with variable spin. Ginzburg, V. L. C.R. Acad. Sci. URSS. 37, 5-6, pp. 166-171, 1942.—By a particle (i, j) is meant one capable of being in the states having spins i, j and masses m_i, m_j respectively. The wave equations are set up and studied for the particles $(\frac{1}{2}, \frac{3}{2})$ and $(1, 2)$, the former being the simplest model of a proton-neutron. The treatment is formulated throughout in the Lagrange form and, at first, in the absence of a field, although this is later introduced.

The theory of the particle of spin $3/2$. V. L. Ginzburg.
J. Phys. (U. S. S. R.) 7, 115-28(1943)(in English).--
The relativistic theory of the particle of spin $3/2$ is developed in spinor-vector form. Expressions are obtained for current density, energy momentum tensor and angular momentum density tensor as well as the operator of spin projection and the complete set of functions for the case of free motion. The interaction of the particle with the electromagnetic field, particularly with the radiation field, is considered. On the basis of a special example the magnetic properties of the particle of spin $3/2$ and of other particles are discussed. P. H. Rathmann

Propagation of Waves

On the Influence of the Terrestrial Magnetic Field on the Reflection of Radio Waves from the Ionosphere. V. L. Ginzburg. *J. Phys. USSR*, 1943, Vol. 7, No. 6, pp. 280-304. The question of the influence of the terrestrial magnetic field on the reflection of radio waves and signals from an inhomogeneous ionized layer (Heaviside layer) is considered (theoretically). In particular the propagation of waves at a small angle to the direction of the magnetic field is investigated, and it is shown that in this case a very peculiar splitting of the reflected signal into three pulses, and not into two, as observed in other cases, must take place.

Scattering of light in helium II. V. L. Ginzburg (*J. Physics, U.S.S.R.*, 1943, 7, 305-306).—The properties of He are explained by Landau's theory, and not as the condensation of a Bose gas. The ratio of intensities of scattered to incident light is given, above 1°K , by the classical formula for ordinary liquids. For He II the velocity (u) of sound waves is given by a quadratic in u : one sound. These waves are considered. For ordinary liquids the scattered light is a triplet, but for He II the central component, corresponding to the "anomalous" waves, is doubled. The inner doublet is both too weak and too close to be resolved. From Landau's equations for sound propagation in He II expressions may be found for the intensity of the individual scattered doublets and their sum. Calc. scattering agrees with experiment.

Propagation of waves

115 ON THE VARIATION IN THE POLARIZATION OF
TWO LAYERS A. E. Ginzburg (Moscow, U.S.S.R.)
(Doklady Akad. Nauk SSSR, 1968, 173, 10, 194-195, 10
English)

Within the last years Khvostikov and others carried out measurements on the polarization of twilight at the zenith. It was found that the dependence of the degree of polarization upon the height of the sun is no monotonic one, but shows several maxima and minima. The position of these maxima and minima, as well as the rest of details in the shape of the curve, vary according to the day, the most deep minimum, however, lies invariably within the region of 25 to 30 km. It has been suggested that polarization anomalies are directly associated with the presence in the stratosphere of ionized layers, and that the decrease in the polarization of light scattered by these layers is due to a sharp increase in the anisotropy of the ionosphere compared to neutral particles. The author finds this interpretation unacceptable. He gives his reasons, among which is the calculation that the light scattered by the ions of the E layer makes up no more than about one ten-thousandth of the total light scattered in this region.

Among the points discussed, "it should be noted that in the course of the twilight there may take place redistribution of density in the atmosphere (polarizing atmosphere), changes in the density gradient [for instance, the gradient of electron concentration in the E layer is known to vary sharply during twilight. This process may be not only a static one, but a dynamic one, i.e., it may prove to be connected with redistribution of the density of the atmosphere], air streams, etc. Dynamical processes of this kind must tell upon changes in the polarization and in the intensity of the light scattered. Moreover, polarization may be affected by meteoric dust, which may be present in considerable amounts at altitudes around 100-150 km... In the course of the day, polarization processes are strongly dependent on the solar activity and on the conditions of illumination of the given region of earth surface by the sun. There is no reason to suppose that these factors play a less important part during twilight. As the state of the ionosphere is also dependent on solar radiation, the existence of a correlation between polarization and the state of the ionosphere is quite natural. The rotation of the polarization plane at high altitudes, which has been observed by Kocubek, as well as its rotation during solar eclipses, stand in need of special explanation and further experimental study. The possibility of the rotation observed being due to fluorescent luminescence of the atmosphere, excited either by solar radiation or by electron impact, cannot yet be rejected." [The rotation of the plane of fluorescence polarization may be due to the influence of the terrestrial magnetic field and to disturbances of normal illumination conditions (changes in the direction of the sun's rays as a result of refraction, etc.).]

On the theory of excited spin states of elementary particles. GINSBURG, V. *J. Phys. USSR*, 8, 1, pp. 33-51, 1944.—A development of the relativistic theory of the particle ($1/2, 1/2$). The cross-section for the scattering of light (or mesons) on the magnetic (or quasi-magnetic) moment of such a particle increases at first with the energy as in the usual theory but becomes constant for photon energies $h\nu \gg (m_1 - m_2)c^2$ where m_1 and m_2 are the rest-masses. Thus, the introduction of higher spin states leads to the cutting-off of the cross-section for scattering and to the possibility of a non-contradictory consideration of the interaction of the heavy particle's moment with the radiation and the meson field. The theory of the particle (1, 2) is also developed and this, together with the above theory, makes it possible to consider the excited states of the proton-neutron and the meson in a relativistic form.

On the wave equations for particles with variable spin.
GINSBURG, V. and BLOKHIN, I. *J. Phys., USSR*, 8, 1, pp. 52-53, 1944. By an (l, j) particle is meant one which can exist in states with spins l and j and with different values of the rest mass. The relativistic wave equations for such a particle, recently proposed by Ginsburg, are said to split up if, by means of a certain transformation of the wave functions, they reduce to a system of equations for a particle with the spin l and for a particle with the spin j , which are independent of each other. It is shown that the equations for a $(0, 1)$ particle and for a $(\frac{1}{2}, \frac{1}{2})$ particle always split up in the absence of a field and also in the case of a certain type of interaction with an electromagnetic field. The equations for a $(1, 2)$ particle are also separable in the absence of a field, but this is not the case for a $(\frac{1}{2}, \frac{1}{2})$ particle.

tion of radio waves in the ionosphere enables one to
determine the effective number of collisions in some
of its regions. On the other hand, it is possible with
the help of the usual method of kinetic equation to
evaluate the number of collisions effective for the
process of absorption of radio waves. Both the
electrons' collisions with the molecules and their
collisions with the ions can be thus calculated.
The cross section for the latter process under con-
ditions prevailing in the ionosphere is about a
million times larger than for collisions with the
molecules. In this connexion the concentration
of ions and molecules in the ionosphere, as derived
from radio measurements, is discussed."

ON THE SURFACE ENERGY AND THE BEHAVIOUR OF SUPRACONDUCTORS OF SMALL DIMENSIONS. V. GINSBURG (J. PHYSICS (U.S.S.R.), 1945, 9, (4), 305-311)
(In English.) Theoretical. The depth of penetration of a magnetic field into a superconductor is discussed, and the effect of the surface energy at the boundary between a superconductor and a vacuum or a metal in the normal state is stressed. It is pointed out that bad agreement between the previous theories and the measured values of the critical fields for superconduction films and massive specimens is due to neglect of the surface-energy factor. The relation between the critical field and the thickness of the film is developed taking this factor into account, and fair agreement with experiment is obtained. GVR.

1. The theory of excited spin states of elementary particles.
V. L. Ginzburg. *Trudy Fiz. Inst., Akad. Nauk S.S.S.R.*,
Phys. Inst., Ser. N. Lebedev 3, No. 2, 163-232 (English
summary, 232-3) (1966) (A dissertation). -- The usual theory
leads to an effective cross section for the scattering of mesons
by heavy particles that increases with energy; this con-
tradicts the exptl. findings. This is due to the fact that the
reaction of the field of the magnetic or quasmagnetic
moment of the scattering particle on the motion of this
moment has been neglected. Accounting for the proper
field in the quantum region leads to the necessity of assum-
ing that the proton and the neutron possess an excited
state with a spin of $3/2$ or higher. In the case of the meson
the assumption of the existence of states with a spin of 2,
etc., arises. In this investigation the relativistic theory of
the particle capable of being in a state with a spin of $1/2$
and rest mass m_1 and in a state with spin $3/2$ and rest
mass m_2 is developed. It is shown that the cross section
for the scattering of light (of mesons) on the magnetic
(quasmagnetic) moment of such a particle at first increases
with the energy as in the usual theory, but then for proton
energies $h\nu \gg (m_2^2 - m_1^2)c^2$ it becomes const. (the recoil
of the heavy particle being neglected). Thus, the intro-
duction of higher spin states, which is adequate to account
for the proper field of the particle moment, leads to the
cutting off of the cross section for scattering and to the
possibility of the interaction of the heavy particle's moment
with the radiation and meson field. The relativistic theory
of a particle having, in one state, a spin of unity and mass
 m_1 and in another state a spin of 2 and mass m_2 has also been
developed. The scattering of light by this model of a
meson has not yet been asked.

818. ON THE DIELECTRIC PROPERTIES OF FERROELECTRIC CRYSTALS AND BARIUM TITANATE.—V. Ginsburg (*J. Physics, U.S.S.R.*, 10, No. 2, 107, 1946). The properties of ferroelectric crystals and of barium titanate are discussed in connection with the thermodynamical consideration of a phase transition from a non-pyroelectrical into a pyroelectrical crystal. Experimental data show that transition in ferroelectric crystals is really of the continuous type, the value of ϵ tending to infinity by approaching the Curie point from either side of this point. Below the transition point (where $T < T_c$) the behaviour of ferroelectric crystals is complicated, as they split into domains the dimensions of which are determined by the condition of the minimum free energy. It is a physical peculiarity of these substances that reversal of the direction of polarisation may be attained in comparatively weak fields which do not exceed a few thousand volt./cm. The characteristic splitting into domains at a given temperature and the physical properties of ferroelectric crystals are determined by the shape of the specimen and the conditions on its boundaries. The problem of saturation, however, remains ambiguous. The large values for ϵ for lattices of the perovskite type accounts for the presence of a small value of Born's frequency, i.e. a certain "looseness" of the lattice, which increases with increasing weight of the metal producing the titanate, and is especially great in the case of Ba, thus contributing to the appearance of pyro-modification. The properties of symmetry of this lattice exclude the possibility of pyro- and piezo-electric phenomena. In BaTiO_3 the Curie point is simultaneously the transition point of a non-piezoelectric into a piezoelectric state. With such transition there should also occur orientational twinning rendering the whole crystal non-piezoelectric. This is known to happen at 573°C. when the transition to β -quartz takes place, its modulus being zero, but unfortunately the phase transition in quartz is of the first type in which ϵ changes by jump but does not possess a sharp temperature dependence. Cooling barium titanate in the absence of an electric field and external stress should lead to a non-piezoelectric state, because of the occurrence of orientational twinning.

Behavior of ferromagnetic substances in the vicinity of the Curie point. V. L. Ginzburg (Acad. Sci. U.S.S.R., Moscow), *Zhur. Eksp. Teor. Fiz.* 17, 833-6 (1947).—Since the ferromagnetic transition near the Curie point θ is a phase transition of the 2nd kind (i.e. without latent heat and with a discontinuous change of the heat capacity), it can be treated in analogy to the previous treatment of the seignette-elec. transition (cf. *C.A.* 40, 5968'). This treatment is free from the arbitrary assumptions underlying the theory of Weiss. From the condition of min. of the thermodynamic potential, the spontaneous magnetization M_s at $T \leq \theta$ is $M_s^2 = -\alpha/\beta = -\alpha'_0 (T - \theta)/\beta_0$, where α and β are functions of the pressure p and of T ; $\alpha'_0 = (\partial\alpha/\partial T)_p = \beta_0 = \beta(p, \theta)$; and $dM_s/dT = \alpha'_0/\beta_0$. In the presence of a field $H = 2\alpha M + 2\beta M^3$, $(\partial M/\partial H)_T = 1/(2\alpha + 6\beta M^2)$, and the initial susceptibility χ , near the Curie point $\chi = 1/2\alpha'_0 (T - \theta)$ or $\chi = 1/4\alpha'_0 (\theta - T)$, at $T > \theta$ or $T < \theta$, resp., i.e. at the same $|T - \theta|$, the susceptibility in the ferromagnetic range is half that in the paramagnetic range. For the heat capacity C_H (at const. M) at $T > \theta$, $C_H dT = T\alpha'_0 d(M^2) = (T/2)[d(1/\chi)/dT]d(M^2)$, and, in the vicinity of the Curie point in a weak field (both at $T > \theta$ and $T < \theta$) $C_H dT = T\alpha'_0 d(M^2)$. Contrary to the Weiss theory, this formula is valid only in the vicinity of θ ; farther from θ ,

Physics Edm t

71

the magnitude α'_0 depends on T . Consequently, α'_0 can be detd. only from the slope of $1/\chi$ in close vicinity θ .

GINSBURG, V. L.

Ginsburg, V. L., and Tamim, I. E. On the theory of spin, Arkiv Fysik, 237 (1947). (Russian)

In a relativistic theory, the state of a particle of spin s is ordinarily given by $2(2s+1)$ wave functions, and the particle, therefore, may be said to possess "internal" degrees of

freedom which are characterized by discrete variables. The authors investigate the case in which the internal degrees of freedom are described by continuous variables.

(1) As a first example, they treat the case where these variables are the components u_i of a space-like four-vector of constant length r . Let x_i ($i=1,2,3,4$) denote the space-time variables ($x_4=ict$), set $\partial_i = \partial/\partial x_i$, $M_{ik} = u_i \partial/\partial u_k - u_k \partial/\partial u_i$, and $L_1 = \frac{1}{2} M_{ik} M_{ik}$. The following equation is suggested:

$$(1) \quad \square - s^2 + \beta L_1 \psi(x_i, u_i) = 0,$$

where $\square = \sum \partial_i^2$, β and s are numerical constants and ψ is assumed to be a scalar function. Product solutions of the form $\psi(x_i, u_i) = \psi(x_i) \varphi(u_i)$ lead to the equations

$$(2) \quad \square \varphi + \lambda \varphi \psi(x_i) = 0, \quad L_1 \varphi = \lambda \varphi.$$

The parameter λ determines the rest mass of the particle, since $m_0^2 c^2 = \hbar^2 \lambda^2$. As in the hydrodynamic $\sum u_i^2 = r^2$, polar coordinates χ, θ, ϕ ($-\infty < \chi < \infty, 0 \leq \theta \leq \pi, 0 \leq \phi \leq 2\pi$) are introduced, $u_1 = r \cosh \chi \sin \theta \cos \phi, u_2 = r \cosh \chi \sin \theta \sin \phi, u_3 = r \cosh \chi \sin \theta \sinh \chi$. Then

$$dS = r^2 \cosh^2 \chi \sin \theta d\chi d\theta d\phi$$

is a Lorentz invariant volume element. To study the second equation (2) the authors determine the square integrable solutions with respect to dS of the form $\varphi(x, \theta, \phi) = R(\chi) Y_{lm}(\theta, \phi)$ (where Y_{lm} is a spherical harmonic). For each $l \geq 1$, a sequence of functions R_{lj} is obtained such that (3a) $\lambda = 1 - j^2$, $j = 1, 2, \dots$; (3b) $l = j+1, \dots$, and the functions R_{lj}/j are orthogonal and normalized. If a square integrable function $\psi(\theta, \phi, \chi)$ may be expanded in a series (4) $\psi = \sum_{lm} a_{lm} Y_{lm} R_{lj}$, then $\int |\psi|^2 dS = \sum_{lm} |a_{lm}|^2$. The Lorentz transform of function is then of the same form, and its square integral remains invariant, i.e., these functions transform according to a unitary infinite dimensional

Source: Mathematical Reviews, 1/3 Vol 9 No. 9

VLG, IET

representation of the Lorentz group. [Reviewers note: The authors neglect the positive continuous spectrum of the operator L_3 and make the erroneous assertion that every square integrable function orthogonal to $Y_{0,0}$ is of the form (4). This oversight, however, hardly affects the main arguments of the discussion.] Since the equation (1) admits infinitely many values of the spin the authors postulate the additional equation (5) $(M_{12}M_{34} - M_{23}M_{14})\psi = 0$, j being a constant. In the particle's rest system the equation (6) $l^2 + l - j - j_0 = 0$ is shown to hold for a fixed value of the angular momentum. The possible spin values are those integers l which satisfy (6) and the condition $l \geq j$ [cf. (3)]. Consequently, j_0 must be an integer. For a given j , the solution $l = j = j_0$ always exists. If $j_0 \neq 5$, a finite number of additional solutions may be found.

(11) The foregoing discussion may be considerably generalized by using the results of I. M. Gelfand and M. A. Neumark on the unitary (infinite dimensional) representations of the Lorentz group. [These results have been published (1946); Izvestiya Akad. Sci. USSR, Ser. Mat. 10, 93-98; 504 (1947); these Rev. 8, 132; 9, 495]. Cf. also Harish-Chandra, Proc. Roy. Soc. London, Ser. A, 189, 572-605 (1947); V. Bargmann, Ann. of Math. (2) 48, 508-640 (1947); these Rev. 9, 132, 133.] The irreducible unitary representations are characterized by the equations

$$\begin{aligned} (7) \quad & \begin{cases} L_3 \psi = \frac{1}{2} M_{12} M_{34} \psi = \lambda_1 \psi, \\ L_2 \psi = -\frac{1}{2} (M_{23} M_{14} + M_{21} M_{34} + M_{12} M_{34}) \psi = \lambda_2 \psi, \end{cases} \\ (7a) \quad & \lambda_1 = 1 - j^2 + \sigma^2, \quad \lambda_2 = -\sigma j, \end{aligned}$$

which hold for every vector ψ in the representation space. The operators $M_{\mu\nu}$ are the corresponding infinitesimal generators.

Creation of mesotrons and "stars" in cosmic rays. V.I. Ginzburg. *Zhur. Eksp. Teor. Fiz.* 17, 943-4 (1947); cf. Alkhanyan, *et al.*, *C.A.* 41, 68054. — A comparison of the production of mesotrons and "stars" indicates that they are generated by the same neutral components of cosmic rays. The no. of "stars" is also nearly the no. of acts of creation of mesotrons per unit time. F. H. Murray

Physics Inst. im. P.N. Lebedev, AN SSSR.

erators of the Lorentz group; their precise form depends on the particular realization which has been chosen, e.g., in terms of vector or spinor quantities. In (7a), α may be any real number, j is integral or half integral (including $j=0$). The equation (3b) remains valid; l characterizes the irreducible representations of the rotation group which occur. Two different sets of j, α lead to inequivalent representations. For the case discussed above, $\alpha=0$. [Reviewer's note. There exist also representations for $\lambda_2=0, 0<\lambda_1<1$, which cannot be expressed in the form (7a).] If the equations (1) and (5) are retained, one obtains in the rest system $(1+j)^2 - j^2 - \delta = 0, \delta = h^2 \alpha^2$. Here δ is positive and integral or half integral including as l (or j) is integral or half integral. Hence α has a finite number of α - and j -values, and consequently only a finite number of spin values appear.

After briefly discussing possible variants of the equations (1) and (5) the authors mention a serious difficulty of the theory proposed. As shown by Fierz and Pauli [Proc. Roy. Soc. London, Ser. A 173, 211-232 (1939); these Rev. 1, 199] the interaction with the electromagnetic field cannot be described by simply replacing $\partial/\partial x_\mu$ by the operator $\Pi_\mu = \partial/\partial x_\mu - (ie/hc)A_\mu$ (A_μ , the components of the four-vector potential) if the spin of the particle is greater than one. Additional wave functions must be introduced, which vanish in the absence of the electromagnetic field. A similar difficulty arises here, and the authors have not yet succeeded in treating the interaction with the electromagnetic field in a satisfactory way.

V. Bargmann (Princeton, N. J.).

1307. Theory of Mesotrons and Nuclear Force, by V. L. Ginsburg, *Uspekhi Fizicheskikh Nauk* 31, No. 2, April 1947. 36 p. (In Russian)

This article is divided into four main sections: Introduction, the wave equations for mesotrons, nuclear force, and difficulties which arise from the present theories. Under the section on wave equations for mesotrons, the author discusses the relation of mesotrons to electromagnetic poles.

The author shows the possibility of obtaining the same radiation effect from nonrelativistic waves as from relativistic waves moving in the field of a dielectric.
